

Business Requirements Document (BRD)

Project Title: Reserve Bank of India (RBI) Sectoral Credit Analytics Platform

Document Owner: Mona Jasuja (Data Analyst)

Target Organization: Commercial Credit Risk & Strategic Analytics Division

Document Version: 1.0

1. Project Context & Business Case

The Reserve Bank of India (RBI) regularly publishes comprehensive datasets mapping credit distribution across commercial banking channels. However, these data assets are typically published in isolated, tabular formats, creating systemic challenges for risk management teams tracking long-term trends.

Current State & Core Challenge

- Data isolation prevents analysts from cross-referencing related credit performance dimensions over multiple years.
- Key reporting values exist at mismatched data grains (e.g., volume values mapped in raw Crores versus quality metrics mapped in percentage variations).
- Manual review of multi-year portfolio profiles results in delayed reporting cycles for executive decision-makers.

Proposed Future State

The objective of this project is to centralize these fragmented financial inputs into a single source of truth database model. This database will supply data directly to a clean interactive interface, allowing management to immediately identify asset exposure, tracking anomalies, and macroeconomic credit velocity shifts between 2018 and 2026.

2. Intended Target Audience

- **Credit Risk Management:** Needs high-level visual tools to monitor total credit footprint distributions and evaluate sector concentration vulnerabilities.
- **Regulatory Compliance Officers:** Require features to separate standard commercial lending from mandated regulatory allocations (Priority Sector Lending).

3. Scope of Work (In-Scope vs. Out-of-Scope)

In-Scope

- Consolidating 9 years (2018–2026) of public RBI sectoral credit deployment data assets.

- Normalizing data attributes by converting mixed structural strings into standardized, chronological calendar Date formats.
- Modelling an operational backend framework using a relational Star Schema design pattern.
- Developing a front-end business intelligence interface to track key credit performance trends.

Out-of-Scope

- Ingesting private or non-public financial institution customer account data.
- Executing real-time streaming updates (data is processed strictly via static extract batches).
- Predictive modelling or machine learning-driven forecasting.

4. Functional Specifications

FS-1: Data Schema Transformation

- The platform must convert all standard numeric year characters into structured calendar Date values (YYYY-MM-DD) to map continuous timelines.
- The relational database must handle missing or empty fields natively inside joint tables without failing or invalidating neighbouring aggregate cell blocks.

FS-2: User Interface Interactivity

- **Cross-Filtering:** Selecting a specific sector row or dimension attribute must instantly trigger cross-filtering across all active chart modules on the page.
- **Dynamic Sizing Parameters:** The interface must support an interactive dropdown toggle allowing users to restrict visual tables to the Top 10 or Bottom 10 sector buckets to prevent vertical layout overflow.
- **Category Extraction:** The design must use string-matching logic to provide a clean toggle for tracking regulatory lending segments (Priority Sector Lending).

5. Non-Functional Specifications

- **Query Performance:** The presentation layout must run queries against optimized database View layers instead of raw processing tables to reduce rendering delays.
- **Layout Consistency:** The visualization layer must use a fixed dashboard canvas resolution to guarantee visual stability across desktop, laptop, and browser viewing contexts.
- **Data Security & Origin:** The infrastructure will handle publicly available macroeconomic data exclusively. No proprietary or confidential banking details can be used within the database.
